1 Exploring the Lorenz System of Differential Equations

In this Notebook we explore the Lorenz system of differential equations:

$$\begin{aligned}\dot{x} &= \sigma(y - x) \\ \dot{y} &= \rho x - y - xz \\ \dot{z} &= -\beta z + xy\end{aligned}$$

This is one of the classic systems in non-linear differential equations. It exhibits a range of different behaviors as the parameters (σ, β, ρ) are varied.

1.1 Imports

First, we import the needed things from IPython, NumPy, Matplotlib and SciPy.

```
In [1]: %matplotlib inline
```

```
In [2]: from IPython.html.widgets import interact, interactive
        from IPython.display import clear_output, display, HTML
```

```
:0: FutureWarning: IPython widgets are experimental and may change in the future.
```

```
In [3]: import numpy as np
        from scipy import integrate

        from matplotlib import pyplot as plt
        from mpl_toolkits.mplot3d import Axes3D
        from matplotlib.colors import cnames
        from matplotlib import animation
```

1.2 Computing the trajectories and plotting the result

We define a function that can integrate the differential equations numerically and then plot the solutions. This function has arguments that control the parameters of the differential equation (σ, β, ρ) , the numerical integration $(N, \text{max_time})$ and the visualization (angle) .

```
In [4]: def solve_lorenz(N=10, angle=0.0, max_time=4.0, sigma=10.0, beta=8./3, rho=28.0):

        fig = plt.figure()
        ax = fig.add_axes([0, 0, 1, 1], projection='3d')
        ax.axis('off')

        # prepare the axes limits
        ax.set_xlim((-25, 25))
```

```

ax.set_ylim((-35, 35))
ax.set_zlim((5, 55))

def lorenz_deriv(x_y_z, t0, sigma=sigma, beta=beta, rho=rho):
    """Compute the time-derivative of a Lorenz system."""
    x, y, z = x_y_z
    return [sigma * (y - x), x * (rho - z) - y, x * y - beta * z]

# Choose random starting points, uniformly distributed from -15 to 15
np.random.seed(1)
x0 = -15 + 30 * np.random.random((N, 3))

# Solve for the trajectories
t = np.linspace(0, max_time, int(250*max_time))
x_t = np.asarray([integrate.odeint(lorenz_deriv, x0i, t)
                  for x0i in x0])

# choose a different color for each trajectory
colors = plt.cm.jet(np.linspace(0, 1, N))

for i in range(N):
    x, y, z = x_t[i,:,:].T
    lines = ax.plot(x, y, z, '- ', c=colors[i])
    plt.setp(lines, linewidth=2)

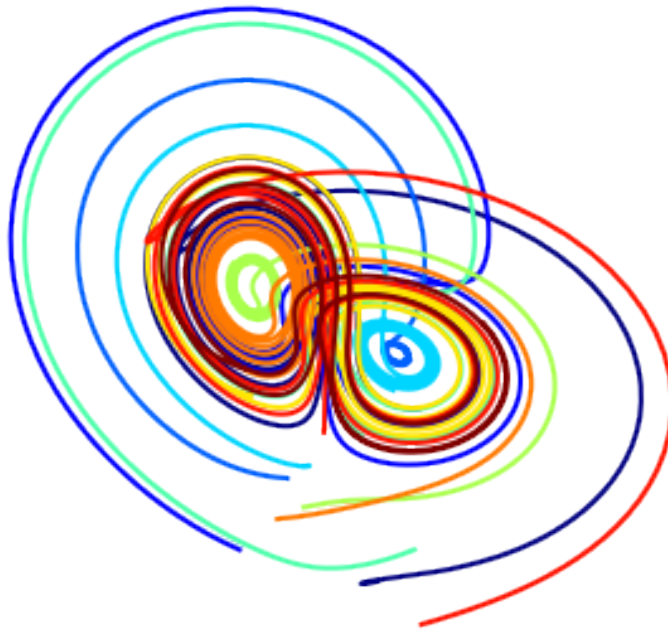

ax.view_init(30, angle)
plt.show()

return t, x_t

```

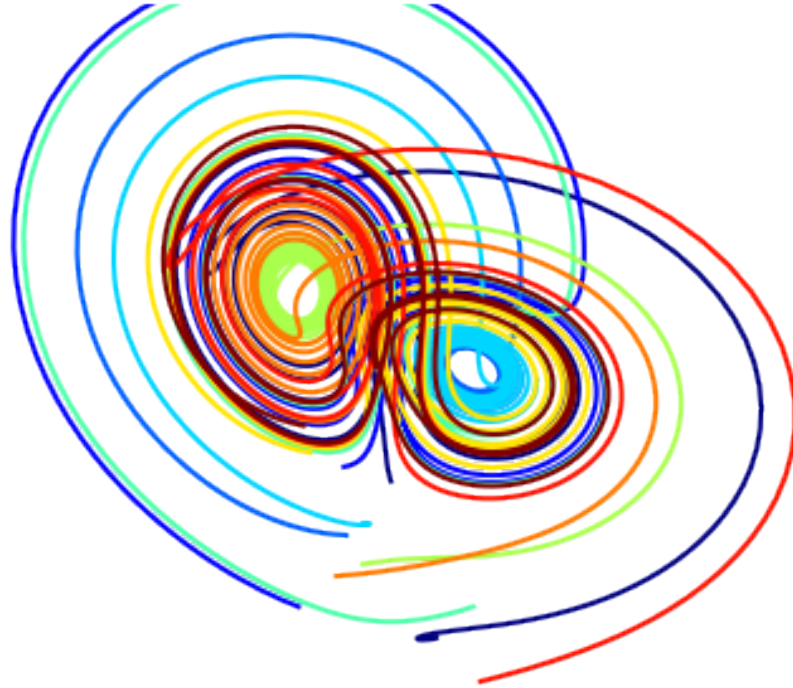

Let's call the function once to view the solutions. For this set of parameters, we see the trajectories swirling around two points, called attractors.

```
In [5]: t, x_t = solve_lorenz(angle=0, N=10)
```

Using IPython's `interactive` function, we can explore how the trajectories behave as we change the various parameters.

```
In [6]: w = interactive(solve_lorenz, max_time=(-4.0,20.0), angle=(0.,360.), N=(10,40), sigma=(0.0,50.0)
        display(w)
```

The object returned by `interactive` is a `Widget` object and it has attributes that contain the current result and arguments:

```
In [7]: t, x_t = w.result
```

```
In [8]: w.kwargs
```

```
Out[8]: {'N': 10,
         'angle': 0.0,
         'beta': 2.6666666666666665,
         'max_time': 4.0,
         'rho': 28.0,
         'sigma': 10.0}
```

After interacting with the system, we can take the result and perform further computations. In this case, we compute the average positions in x , y and z .

```
In [9]: xyz_avg = x_t.mean(axis=1)
```

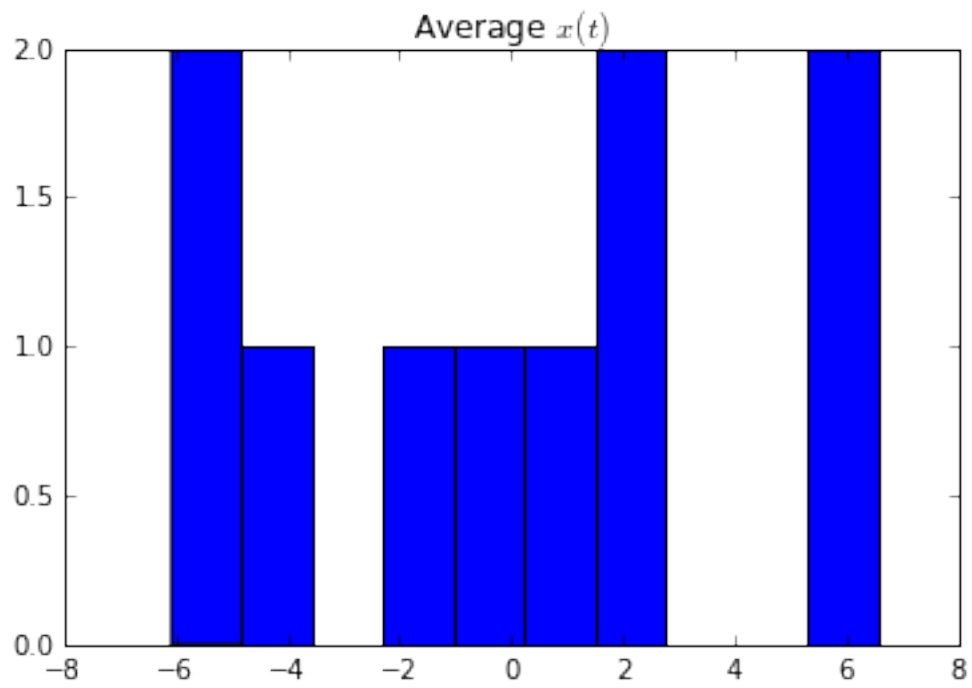

```
In [10]: xyz_avg.shape
```

```
Out[10]: (10, 3)
```

Creating histograms of the average positions (across different trajectories) show that on average the trajectories swirl about the attractors.

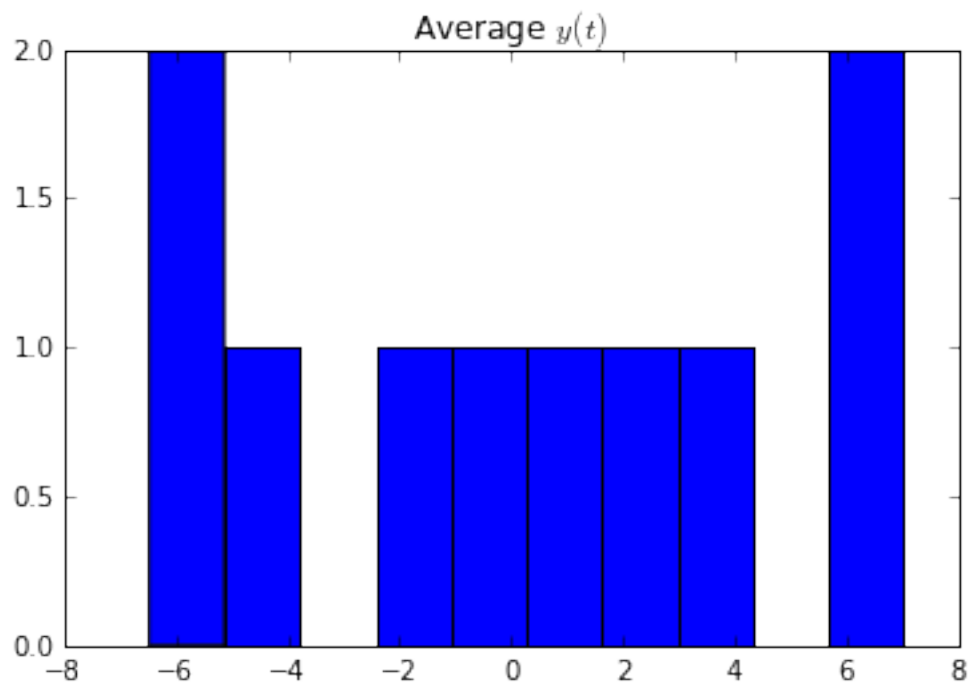

```
In [11]: plt.hist(xyz_avg[:,0])
         plt.title('Average $x(t)$')
```

```
Out[11]: <matplotlib.text.Text at 0x111b7af98>
```

```
In [12]: plt.hist(xyz_avg[:,1])
         plt.title('Average  $y(t)$ ')
```

```
Out[12]: <matplotlib.text.Text at 0x111d80710>
```
